

COUNTING SORT: assume input: n integers within range of size k

Use an array with k indices matching range

↳ keep track of how many integers have each value

stable sorting

COUNTING SORT: **assume** input: n integers within range of size k

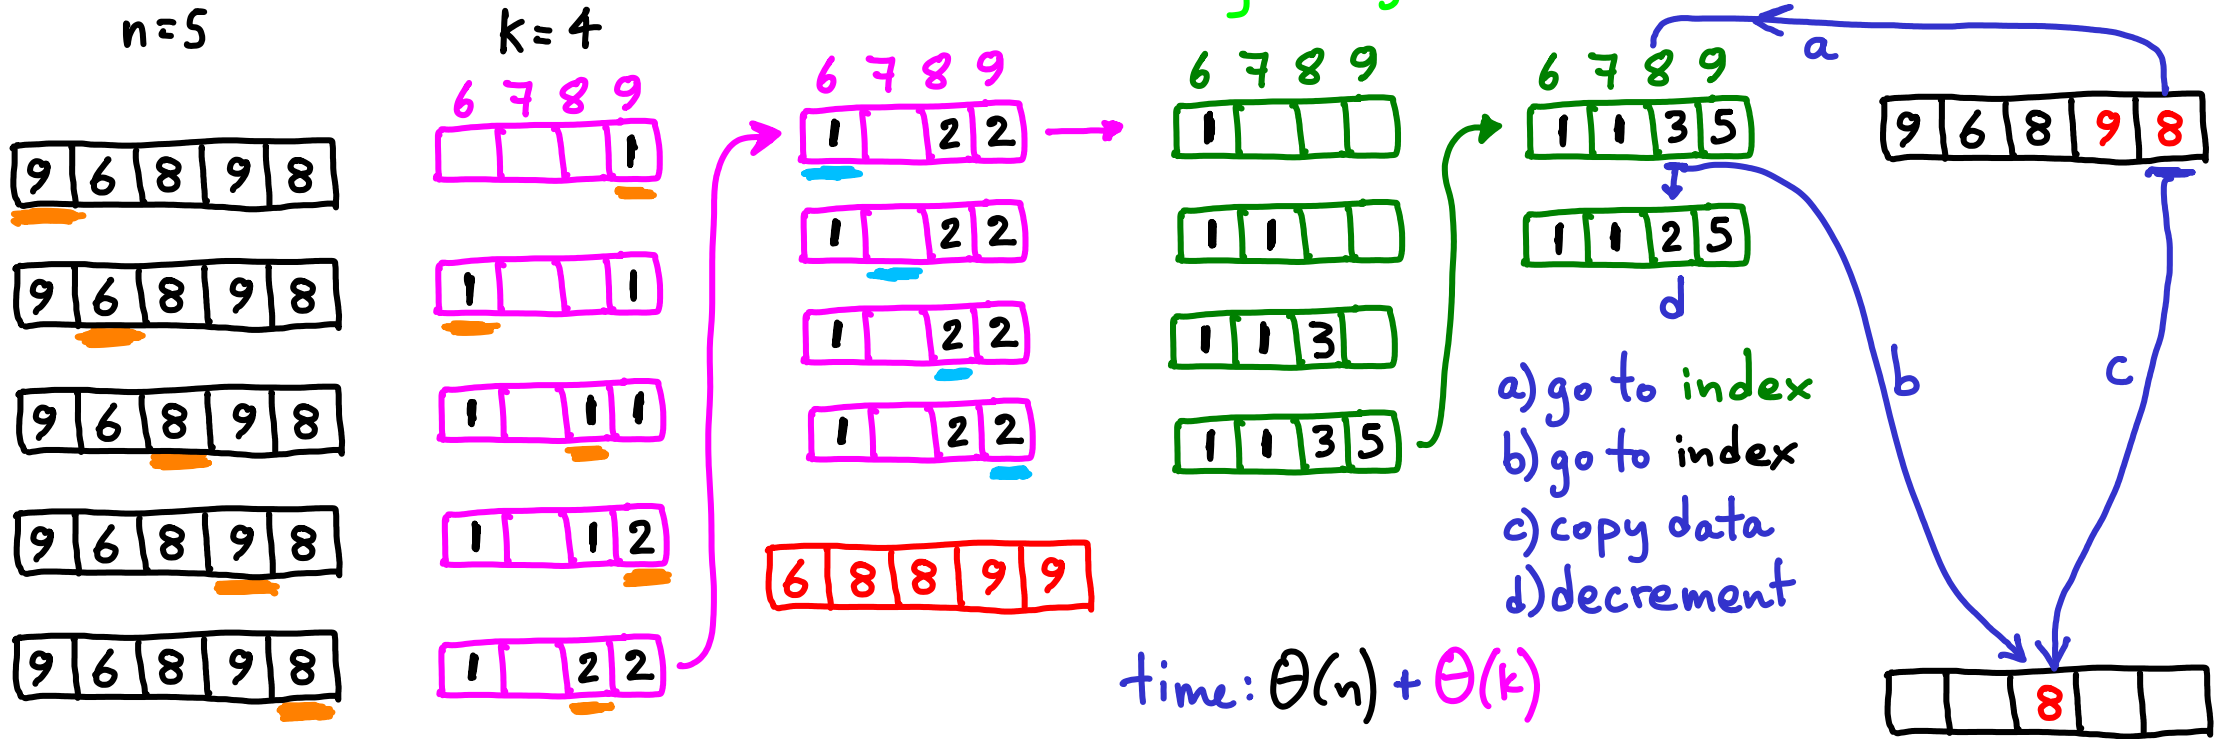

Use an **array** with k indices matching range

↳ keep track of how many integers have each value

Use a second array of size k to get stable sorting

↳ how many integers are \leq each value

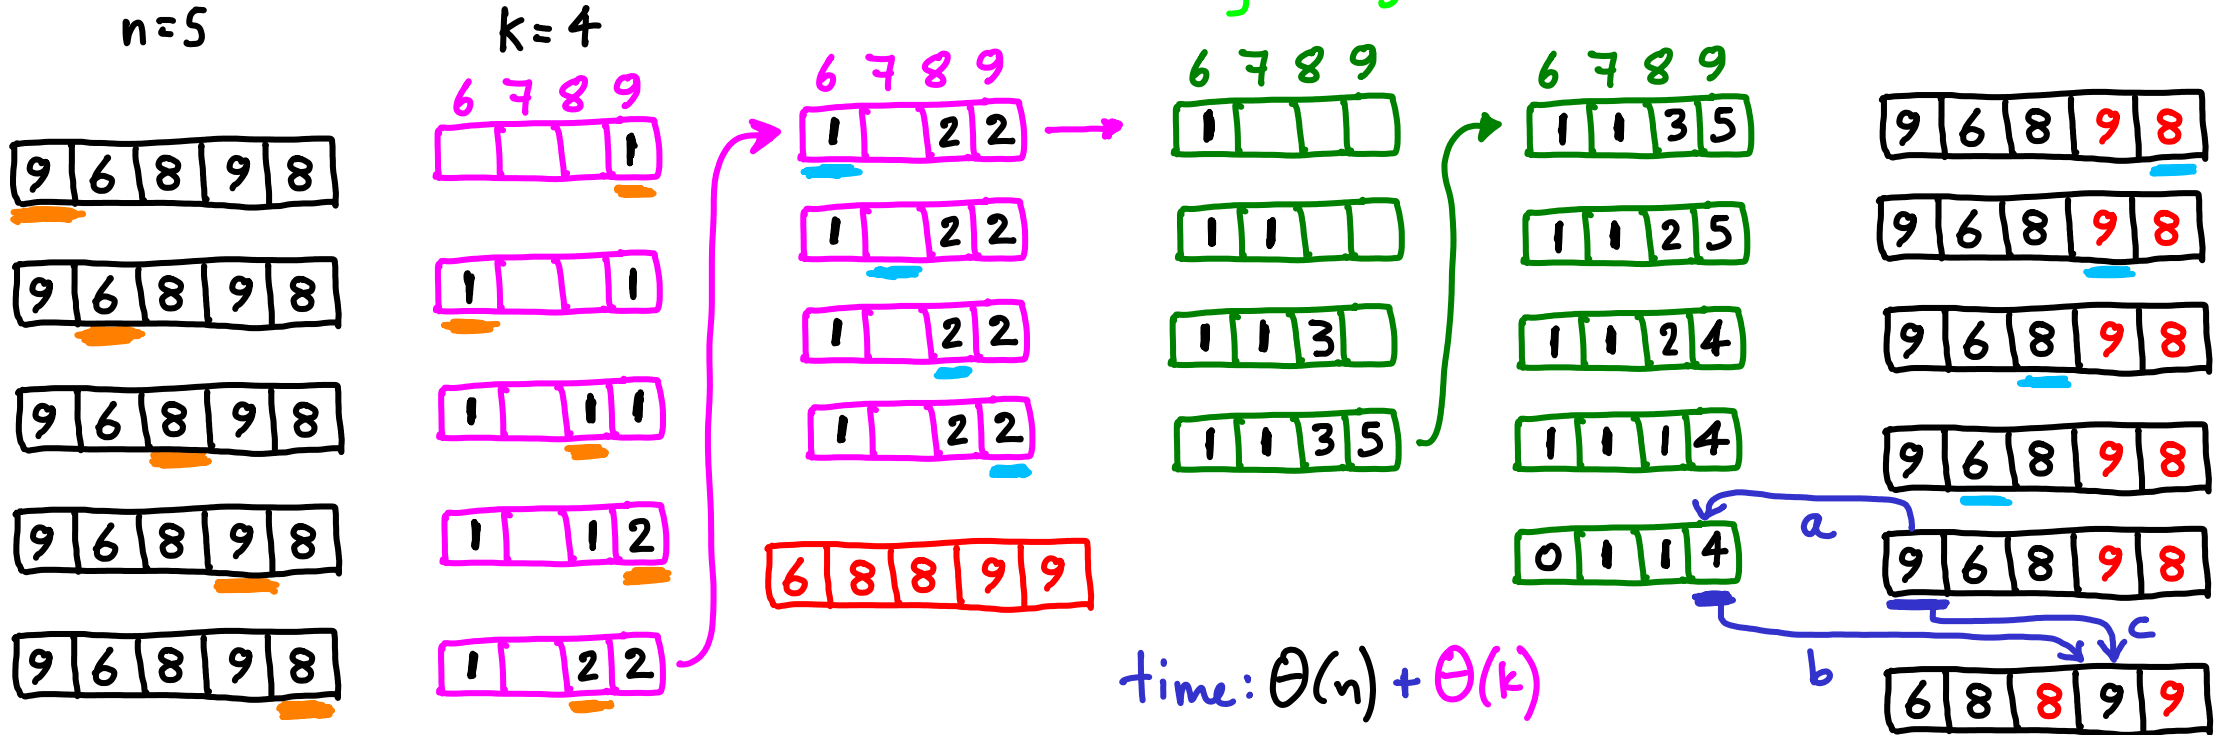

COUNTING SORT: **assume** input: n integers within range of size k

Use an **array** with k indices matching range

↳ keep track of how many integers have each value

Use a second array of size k to get stable sorting

↳ how many integers are \leq each value

STABLE COUNTING SORT recap

the first time we point to the count array at index i ...
 ... it tells us where the last element with value i must go

Then we decrement so the next element with value i (to the left in input array) will have its correct empty place.

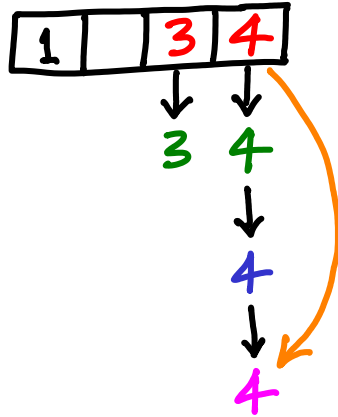

We will only decrement once per element with value i , so we maintain $\#$ in index $i > \max \#$ in index $i-1$
 no conflicts

There is also a similar variant in which we use a helper array to record the leftmost target position for each value. (Omitted here)

A different version follows.

linked list

need a pointer
to last element
in linked list
otherwise $O(n^2)$

trivial
→

$O(n)$ for all
linked lists
+ $O(k)$ just to
create the
counter array

RADIX SORT

n : number of elements

l : (max) length of each element

r : radix (#symbols available at each digit) e.g., binary, decimal, hex

1073	284	5	8261	2714	382
------	-----	---	------	------	-----

1073	0284	0005	8261	2714	0382
------	------	------	------	------	------

$r = 9$
(0...8)

$l = 4$

$n = 6$

There is a version of Radix sort
that does what most of us find intuitive:

Group all elements by most significant digit
& recurse within each group.

There is another way that is easier to implement.

RADIX SORT

3 2 9

4 5 7

6 5 7

8 3 9

4 3 6

7 2 0

3 5 5

$$n = 7$$

$$l = 3$$

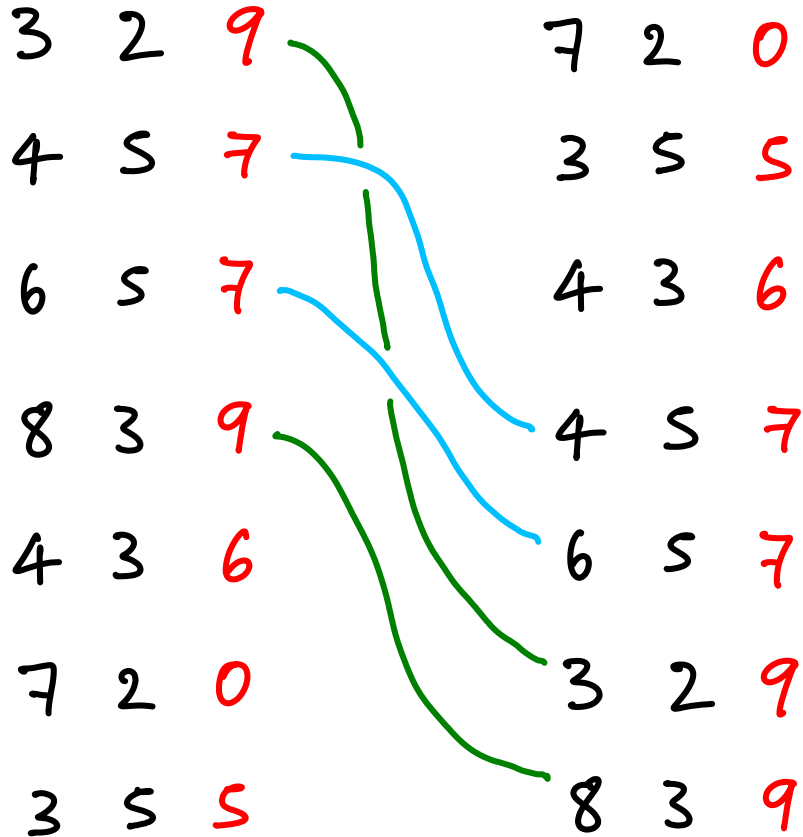

$$r = 10$$

RADIX SORT

uses the least significant digit.

use stable counting sort

→ $\Theta(n+r)$

RADIX SORT

uses the least significant digit.

iteration 2

Assume by induction:

after iteration i you have sorted all elements by the last i digits.

Then stable sort preserves correct order if there are ties at digit $i+1$
